

Critique

Using modeling on Timeseries data. The columns and stock price columns need to be defined in a way that is readable to the user. The prediction for this in both series are showing specific expected values for the time the graphs were created. There is no range of values for best/ worst case scenarios.

Comparing the model performances does not really show the values in this. The margin for error on these models could be anything. Upper and lower bounds to try and predict the equivalent of the future and how 'narrow' that confidence band is would be an effective way to showcase the model's true performance.

Inherently predicting the future is impossible and accuracy over time diminishes. The farther you try to predict the less information about the past can be used. Its similar to building a staircase on absolutely no foundation. Probably OK for the first few steps into the future but will enevitably fall apart.
